	Women Representation in City Property of San Fransisco, an Exploration Welcome! This notebook will follow the process of initially exploring a dataset regarding the gender distribution of monuments in San Fransisco. Let's start by loading in the packages we will need.
In [1]:	<pre>import pandas as pd import numpy as np import matplotlib.pyplot as plt import seaborn as sns</pre> Now let's load in our data and get it's dimensions.
	<pre>df = pd.read_csv("C:/Users/IB/Desktop/data analysis/kaggle/women_rep_sf/WomenRepresentaionInCityPropert y-SanFrancisco.csv") df.shape (82, 11) Let's take a look at the important characteristics of each column.</pre>
<pre>In [3]: Out[3]:</pre>	<pre>col_chr = pd.DataFrame({"Data Type":df.dtypes,</pre>
	Department/Sourceobject08Nameobject082Personobject169Genderobject05Referenceobject2821
	Commentsobject5013Current Police Districtsint6401Current Supervisor Districtsint6401Analysis Neighborhoodsint6401Neighborhoodsint6401SF Find Neighborhoodsint6401
In [4]:	Note that the final 5 columns consist of only a single possible observation, with no NA values. Let's print the single observations for each of these variables.
Out[4]:	Current Police Districts 4 Current Supervisor Districts 10 Analysis Neighborhoods 36 Neighborhoods 21 SF Find Neighborhoods 21 Name: 1, dtype: int64 Now let's rename our columns and drop the uninteresting variables.
In [5]:	<pre>df_final = df.drop(df.columns[6:11],axis=1).rename(columns={"Department/Source":"dep_source",</pre>
Out[5]:	dep_source name person gender ref comments 0 Administrator MOSCONE CENTER (South) George R. Moscone M City Administrator NaN 1 Administrator Maxine Hall Health Center NaN F Public Health NaN 2 REC AND PARKS Moscone Recreation Center George R. Moscone M NaN park
	3 REC AND PARKS Helen Crocker Russell Library of Horticulture, Helen Crocker F NaN facilities and other amenities 4 REC AND PARKS Sharon Building, Golden Gate Park Sharon Building M NaN facilities and other amenities Let's look at the columns in the order they are presented here. So, we will start with the Department column. Note that since this dataset focuses on gender, we can include a breakdown of each column with the associated genders they represent.
In [6]: Out[6]:	Data Type object NA's 0 Unique Values 8 Name: Department/Source, dtype: object With 8 unique values and no NA's, we can see that the important question is how these observations are distributed.
In [7]:	<pre>dep = df_final.dep_source.value_counts() dep = dep.to_frame() plt.ylabel('Department') plt.xlabel('Monuments/Statues') plt.title('Distribution of Department Sources in SF Monuments') plt.barh(dep.index,dep.dep_source)</pre>
Out[7]:	Object of 8 artists> Distribution of Department Sources in SF Monuments AIRPORT Port PuC
	RED - SFMTA - LIBRARY - REC AND PARKS - Administrator - 0 10 20 30 40
In [8]:	Monuments/Statues Now let's check out the gender breakdown for the Department/Source column.
Out[8]:	<pre>.rename(columns={0:"Count","dep_source":"Department/Source"}) plt.xticks(rotation=45) sns.barplot(x="Department/Source",y="Count",hue="gender",</pre>
	30 -
	10 - 5 - 6 - 15 - 10 - 10 - 10 - 10 - 10 - 10 - 10
In [9]:	Department/Source Now let's look at the "name" column, which describes the location of each monument. col_chr.loc["Name"]
Out[9]:	Data Type object NA's 0 Unique Values 82 Name: Name, dtype: object With 82 unique values, each observation is a unique string. This column would perhaps be useful with a locational dataset to merge with, but on it's own doesn't give us much information.
	As such, let's continue on to the next column; the "person" column, which denotes who the statue is of. col_chr.loc["Person"] Data Type object NA's 1 Unique Values 69 Name: Person, dtype: object
	Let's take a look at how many times various individuals are honored with a statue. The "person" column denotes who the subject is, so we will create a frequency histogram of said column. However, note that there are some statues of multiple people, so it is important to code a solution with this in mind. Here we will begin by revealing all the multi-person statues, and the individual statues that also honor those individuals.
in [11]:	<pre>multiples = df_final.loc[(df_final['gender']=="F & M") </pre>
	<pre>multiples.iloc[3].person_1 = "Walter Hass" multiples.iloc[4].person_2 = "Syncip Family" multiples.iloc[5].person_2 = "Koret (Family?)" multiples.iloc[6].person_1 = "Herman Herbst" multiples.iloc[7].person_2 = "Fulton (family?)" multiples.iloc[8].person_1 = "Dianne Taube" multiples.iloc[9].person_1 = "Thelma Doelger" multiples=multiples.person_1.append(multiples.person_2).reset_index(drop=True)</pre>
Out[11]:	<pre>multiples=" ".join(multiples) df_final[df_final['person'].str.contains(multiples,na=False)] c:\users\ib\appdata\local\programs\python\python38\lib\site-packages\pandas\core\strings.py:1954: Use rWarning: This pattern has match groups. To actually get the groups, use str.extract. return func(self, *args, **kwargs) dep_source</pre>
	5 Administrator Priscilla Chan and Mark Zuckerberg San Francis Priscilla Chan and Mark Zuckerberg F & M Public Health NaN 7 REC AND PARKS Minnie & Lovie Ward Recreation Center Minnie & Lovie Ward F & M NaN park 26 Administrator Charlotte and George Shultz Horseshoe Drive Charlotte and George Shultz F & M War Memorial Opera House NaN

	We have looked through every name in the person column, and it seems that no person that is the subject of a multi-individual statue is also the subject of a single subject statue. This makes things much easier, but we still have to decide whether to treat these multi-person statues as two separate observations or as a single. Since many of these people multi-person statues are of two partners, or of an unknown number of people under the denotion of a family, it is a wise choice to treat each multi-statue monument as a single individual instead of portioning into each unique individual.
In [12]:	So, let us plow ahead and look at the distribution of repeated individuals in San Fransisco Monuments. person_ftable = df_final.person.value_counts().to_frame() plt.hist(person_ftable.person, density=False) plt.xlabel('Times a Person is Repeated') plt.ylabel('Unique persons') plt.title('Frequency Histogram of Repeated Persons') plt.show()
	Frequency Histogram of Repeated Persons 60 -
	30 - 10 - 10 - 10 - 10 - 10 - 10 - 10 -
<pre>In [13]: Out[13]:</pre>	One person was embodied 6 times in various monuments. Let's see who it was. person_ftable.loc[person_ftable["person"]==6].index[0] 'George R. Moscone'
In [14]:	George Moscone was the mayor of San Fransisco from 1976 until 1978 when he was assassinated. It makes sense that he would be honored more than the average individual. Let's look at the distribution of genders in monuments. Note that there is a subset of statues that include more than one person, specifically those with two males or one of each male and female subjects. gender_ftable = df_final.gender.value_counts().to_frame().reset_index().replace({"index":{"M & F":"F & M"}}).groupby("index",sort = False).sum()
	<pre>x_axis_order = ["M & M", "M", "F & M", "F"] plt.xlabel('Gender Combinations') plt.ylabel('Monuments/Statues') plt.title('Distribution of Gender in SF Monuments') plt.text("F & M", 40, "M only = 54", fontsize=10) plt.text("F & M", 45, "F only = 19") plt.text("F & M", 35, "Both = 8") plt.bar(gender_ftable.loc[x_axis_order].index,</pre>
Out[14]:	<pre>color = ['red', 'red', 'purple', 'blue']) <barcontainer 4="" artists="" object="" of=""> Distribution of Gender in SF Monuments Fonly = 19 Monly = 54</barcontainer></pre>
	WounderstyStatus Both = 8 10 -
	M & M F & M F Gender Combinations Here we can see that there are more statues of men than there are of women. Let's move on to the reference column.
<pre>In [15]: Out[15]:</pre>	Col_chr.loc["Reference"] Data Type object NA's 28 Unique Values 21 Name: Reference, dtype: object
In [16]:	<pre>plt.hist(ref_ftable.ref, density=False) plt.xlabel('Times a Reference is Repeated') plt.ylabel('Unique References') plt.title('Frequency Histogram of Repeated References')</pre>
	Frequency Histogram of Repeated References 10 - 8 - 8 - 8 - 8 - 8 - 8 - 8 - 8 - 8 -
	6 - 4 - 4 - 4 - 4 - 4 - 4 - 4 - 4 - 4 -
In [17]:	Times a Reference is Repeated So, we can see a right-skewed histogram which is more spread out than the person column. There seem to be 3 references repeated 5 times or more. Let's take a look at each: ref_ftable[ref_ftable["ref"]>=5]
Out[17]:	Municipal Transportation Agency 9 City Administrator 8 Veterans Building 5
In [18]:	Now let's conduct a gender breakdown of the reference column. There are a lot of them, so lets include only references associated with more than 1 statue. ref_gender2=df_final.groupby(["ref", "gender"]).size() \
	<pre>ref_gender_final=ref_gender2[ref_gender2["Reference"].str.contains(ref_considered)] sns.barplot(y="Reference", x="Count", hue="gender",</pre>
Out[18]:	return func(self, *args, **kwargs) <axessubplot:xlabel='count', ylabel="Reference"> City Administrator Davies Symphony Hall Municipal Transportation Agency</axessubplot:xlabel='count',>
	Port - Public Health - Public Library - Public Utilities Commission - Public Works - Veterans Building - War Memorial Opera House -
In [19]:	Now we can move on to the comments column: col_chr.loc["Comments"]
	Data Type object NA's 50 Unique Values 13 Name: Comments, dtype: object Again, we will plot a distribution of how often various comments are repeated.
In [20]:	<pre>com_ftable = df_final.comments.value_counts().to_frame() plt.hist(com_ftable.comments, density=False) plt.xlabel('Times a Comment is Repeated') plt.ylabel('Unique Comments') plt.title('Frequency Histogram of Repeated Comments') plt.show()</pre> Frequency Histogram of Repeated Comments
	Onique Comments 7 - 6 - 4 - 4 - 4 - 4 - 4 - 4 - 4 - 4 - 4
	Here there are 3 comments repeated 3 or more times. Let's look at what they were.
In [21]: Out[21]:	com_ftable[com_ftable["comments"]>=3] comments facilities and other amenities 11 park 6
	Library 3 It seems that this information might denote the environment of a monument. Let's do a gender breakdown of the comments column, again only considering comments that occur more than once.
In [22]:	<pre>com_gender2=df_final.groupby(["comments", "gender"]).size() \</pre>
Out[22]:	<pre>data=com_gender_final, hue_order=["M","F & M","F"], palette=["Red","grey","blue"],orient="h") <axessubplot:xlabel='count', ylabel="Comment"> Family-</axessubplot:xlabel='count',></pre>
	Not in SF Data - facilities and other amenities - gender M F & M
	That concludes a case by case examination of each individual column. There is a lot of possibilities in terms of merging with other datasets, such as perhaps locational data.
	Thanks to Ashwani Rathee for submitting the data to kaggle: https://www.kaggle.com/ashkhagan/women-representation-in-city-property-sanfrancisco Original Data Source: "Representation of Women in City Property - City Administrator's List."
